Definition

A **recursive** predicate is a predicate that calls itself.

```
rec_pred(x_1, x_2, ..., x_n) :-
```

```
    goal_1,
```

```
    ...,
```

```
    goal_p,
```

```
    rec_pred(y_1, y_2, ..., y_n),
```

```
    goal_p_1,
```

```
    ...,
```

```
    goal_q.
```

A predicate is **tail recursive** if the recursive call is the last goal in each recursive rule.

Example 1 – Factorial

Mathematical Definition

Assignment Project Exam Help

$$n! = 1 \times 2 \times 3 \times \dots \times (n-1) \times n$$
$$n! = (n-1)! \times n$$

Prolog Implementation

```
factorial(N, FN) :-
```

```
    M is N-1,
```

```
    factorial(M, FM),
```

```
    FN is N*FM.
```

Add WeChat powcoder

Can you spot the problem?

Example 1 – Factorial

Prolog Implementation – Corrected

```
factorial(0, 1).
```

```
factorial(N, FN) :-
```

```
    N > 0,
```

```
    M is N-1,
```

```
    factorial(M, FM),
```

```
    FN is N*FM.
```

Do not forget the base case!

Usually, the base case(s) is/are placed *before* the recursive case(s).

Loops do not exist in Prolog, you have to use recursion!

Assignment Project Exam Help

C++

```
while(i<n) {  
    // do A  
    ++i;  
}  
// do B
```

Prolog

```
while_loop(I, N, X1, X2, ...) :-  
    I == 1,  
    % do B
```

```
while_loop(I, N, X1, X2, ...) :-  
    I < N,  
    % do A  
    NewI is I+1,  
    while_loop(NewI, N, Y1, Y2, ...).
```

Example 2 – Ackermann's Function

Mathematical Definition

$$A(m, n) = \begin{cases} n+1 & \text{if } m=0 \\ A(m-1, 1) & \text{if } m>0 \text{ and } n=0 \\ A(m-1, A(m, n-1)) & \text{if } m>0 \text{ and } n>0 \end{cases}$$

Prolog Implementation – Revisited

```
ackermann(0, N, R) :-      ackermann(M, N, R) :-
    R is N+1.              M > 0, N > 0,
                             N1 is N-1,
ackermann(M, 0, R) :-      ackermann(M, N1, R1),
    M > 0,                 M1 is M-1,
    M1 is M-1,              ackermann(M1, R1, R).
    ackermann(M1, 1, R).
```

Different flavours of recursion

Program 1

```
natural_number(0).  
  
natural_number(N) :-  
    natural_number(M),  
    N is M+1.
```

Program 2

```
natural_number(0).  
  
natural_number(N) :-  
    natural_number(M),  
    M is N-1.
```

Program 3

```
natural_number(0).  
  
natural_number(N) :-  
    N is M+1,  
    natural_number(M).
```

Program 4

```
natural_number(0).  
  
natural_number(N) :-  
    M is N-1,  
    natural_number(M).
```

Assignment Project Exam Help

	Test	Generate	Remark
Program 1	✓	✓	Slower than Program 4
Program 2	✗	✗	
Program 3	✗	✗	Tail recursive, but does not work
Program 4	✓	✗	Tail recursive, most efficient (for testing)

Why is the tail recursive predicate much faster?

Why is the tail recursive predicate much faster?

Computing '`nn1(N)`' will take $N(N-1)/2$ additional steps compared to '`nn4(N)`'

Hint:

How would you code factorial in an imperative language?

Non tail-recursive version

```
factorial(0, 1).
```

```
factorial(N, FN)
```

$N > 0$,

M is $N-1$,

$\text{factorial}(M, FM)$,

FN is $M \cdot FM$.

How to make factorial tail-recursive?

C/C++ version

```
int factorial(int n) {  
    int x = 1;  
    while(n > 0) {  
        x *= n;  
        --n;  
    }  
    return x;  
}
```

Solution: use an *accumulator*!

Assignment Project Exam Help

Tail-recursive version

```
factorial(N, FN) :-  
    trf(N, 1, FN).
```

```
trf(0, Acc, Res) :-
```

```
    Res is Acc.
```

```
trf(N, Acc, Res) :-
```

```
    N > 0,
```

```
    NewAcc is Acc * N,
```

```
    M is N-1,
```

```
    trf(M, NewAcc, Res).
```

```
-----> return acc;
```

```
-----> while(n > 0) {
```

```
----->     acc *= n;
```

```
----->     --n;
```

```
-----> }
```

Factorial revisited

Tail-recursive version

```
factorial(N, FN) :-  
    trf(N, 1, FN).  
trf(0, Acc, Res) :-  
    Res is Acc.  
trf(N, Acc, Res) :-  
    N > 0,  
    M is N-1,  
    NewAcc is Acc * N,  
    trf(M, NewAcc, Res).
```

?- factorial(4, F).

?- trf(4, 1, F).

?- 4 > 0,
 M is 4-1,
 NewAcc is 1*4,
 trf(M, NewAcc, F).

?- trf(3, 4, F).

?- trf(2, 12, F).

?- trf(1, 24, F).

?- trf(0, 24, F).

■ F = 24

Assignment Project Exam Help

- Do not forget the base case.
- Think about how you will use your predicate (and in particular, which arguments will be ground).
- The order of the rules, the calls in the rules and the calls in the query are extremely important (both for recursive and non-recursive procedures): try to design tail-recursive programs.
- Use `trace` to see how your predicate is working.

Declarative vs. Procedural Meaning

Consider the rule ' $A :- B, C.$ '

- Declarative meaning (logical interpretation):
 $A \leftarrow B \wedge C$, i.e. A is true if B is true and C is true

- Procedural Meaning (how Prolog interprets the rule):
to prove A , prove B and **then** prove C (order matters!).

Consider the rules ' $A :- B.$ ' and ' $A :- C.$ '

- Declarative meaning: $A \leftarrow B \vee C$
- Procedural meaning: to prove A , prove B . If B does not hold, then to prove A , prove C (again, order matters!).

Example: ' $p :- p.$ '

- Declarative meaning: $p \leftarrow p$ (tautology)
- Procedural meaning: to prove p , prove p ... Infinite loop!

Assignment Project Exam Help

Consider the program P and the query Q

	Prolog	Logic
Q ground	yes. no.	$P \models Q$ $P \not\models Q$
Q contains variables	θ (Prolog outputs a valid substitution) no.	$P \models \forall X_1, \dots, X_k (Q\theta)$ $\forall \theta, P \not\models \forall X_1, \dots, X_k (Q\theta)$
